

Block Cipher Operation

1 OVERVIEW

The learning objective of this lab is to get familiar with the block cipher operations. The lab focuses on encryption algorithms, encryption modes, paddings, initialization vector and error propagation.

You need to take screenshots of key steps and answer questions for your lab report. For the weekly lab, you can discuss with your group. However, you need to prepare your report with your own screenshots. You have one week to prepare your report. Please submit your report to Canvas.

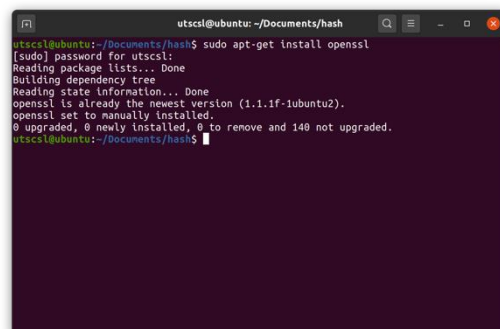

2 PRELIMINARIES

2.1 Install openssl

OpenSSL is a robust, commercial-grade, and full-featured toolkit for the Transport Layer Security (TLS) and Secure Sockets Layer (SSL) protocols. It is also a general-purpose cryptography library. More information about openssl can be found in <https://www.openssl.org/>

Install openssl, if openssl has not been installed, with the following command

\$ sudo apt-get install openssl

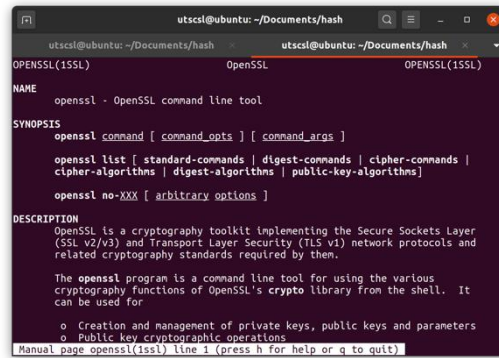

```
utscsl@ubuntu: ~/Documents/hash
utscsl@ubuntu:~/Documents/hash$ sudo apt-get install openssl
[sudo] password for utscsl:
Reading package lists... Done
Building dependency tree
Reading state information... Done
openssl is already the newest version (1.1.1f-1ubuntu2).
openssl set to manually installed.
0 upgraded, 0 newly installed, 0 to remove and 140 not upgraded.
utscsl@ubuntu:~/Documents/hash$
```

Check the manual page on the openssl and supported algorithms and more options with the following command

\$ man openssl

Cryptography

2.2 Install bless

We will be using a tool called bless to view encrypted files in hexadecimal. To install this tool, you can use:

```
$ sudo apt-get install bless
```

3 TASKS

3.1 Encryption using Different Ciphers and Modes

In this task, we will play with various encryption algorithms and modes. You can use the following *openssl enc* command to encrypt/decrypt a file. To see the manuals, you can type *man openssl* and *man enc*.

```
$ openssl enc -ciphertext -e -in plain.txt -out cipher.bin -K 00112233445566778889aabbccddeeff -iv 0102030405060708
```

Please replace the *ciphertext* with a specific cipher type, such as *-aes-128-cbc*, *-bf-cbc*, *-aes-128-cfb*. In this task, you should try at least 3 different ciphers. You can find the meaning of the command-line options and all the supported cipher types by typing "*man enc*". We include some common options for the *openssl enc* command in the following:

-in <file>	input file
-out <file>	output file
-e	encrypt
-d	decrypt
-K/-iv	key/iv in hex is the next argument
-[pP]	print the iv/key (then exit if -P)

3.2 Encryption Mode – ECB vs. CBC

We would like to encrypt *uts.bmp*, so people without the encryption keys cannot know what is in the picture. Please encrypt the file using the ECB (Electronic Code Book) and CBC (Cipher Block Chaining) modes, and then do the following:

Cryptography

Encrypt the image using the ECB (Electronic Code Book) and CBC (Cipher Block Chaining) modes, save them separately (you can name the encrypted files ecb.bmp and cbc.bmp).

We can use the bless hex editor tool to directly modify binary files. We can also use the following commands to get the header from ecb.bmp, the data from cbc.bmp (from offset 55 to the end of the file), and then combine the header and data together into a new file.

Display the encrypted picture using a picture viewing program.

Q: Can you derive any useful information about the original picture from the encrypted picture? Please explain your observations.

An example is given below

```
utscsl@ubuntu: ~/Documents/Encryption
utscsl@ubuntu: ~/Documents/Encryption
utscsl@ubuntu: ~/Documents/Encryption$ openssl enc -aes-128-cbc -e -in uts.bmp -out cbc.bn
p -K 00112233445566778899aabbccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
utscsl@ubuntu: ~/Documents/Encryption$ openssl enc -aes-128-ecb -e -in uts.bmp -out ecb.bn
p -K 00112233445566778899aabbccddeeff -iv 0102030405060708
warning: iv not used by this cipher
utscsl@ubuntu: ~/Documents/Encryption$ tail -c +55 ecb.bmp > ecbBody
utscsl@ubuntu: ~/Documents/Encryption$ tail -c +55 cbc.bmp > cbcBody
utscsl@ubuntu: ~/Documents/Encryption$ head -c 54 uts.bmp > header
utscsl@ubuntu: ~/Documents/Encryption$ cat header cbcBody>cbcRecover.bmp
utscsl@ubuntu: ~/Documents/Encryption$ cat header ecbBody>ecbRecover.bmp
```

3.3 Padding

For block ciphers, when the size of a plaintext is not a multiple of the block size, padding may be required. All the block ciphers normally use PKCS#5 padding, which is known as standard block padding. We will conduct the following experiments to understand how this type of padding works:

Cryptography

Use ECB, CBC, CFB, and OFB modes to encrypt a file (you can pick any cipher). Please report which modes have paddings and which ones do not. For those that do not need paddings, please explain why.

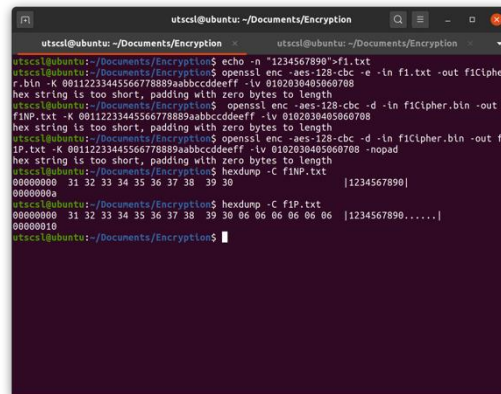

Let us create two files, which contain 10 bytes, and 16 bytes, respectively. We can use the following "echo -n" command to create such files. The following example creates a file f1.txt with length 10 (without the -n option, the length will be 11, because a newline character will be added by echo):

```
$ echo -n "1234567890" > f1.txt
```

We then use "openssl enc -aes-128-cbc -e" to encrypt these three files using 128-bit AES with CBC mode. Please describe the size of the encrypted files.

We would like to see what is added to the padding during the encryption. To achieve this goal, we will decrypt these files using "openssl enc -aes-128-cbc -d". Unfortunately, decryption by default will automatically remove the padding, making it impossible for us to see the padding. However, the command does have an option called "-nopad", which disables the padding, i.e., during the decryption, the command will not remove the padded data. Therefore, by looking at the decrypted data, we can see what data are used in the padding. Please use this technique to figure out what paddings are added to the two files.

An example is given as below

```
utscsl@ubuntu: ~/Documents/Encryption
utscsl@ubuntu:~/Documents/Encryption$ echo -n "1234567890">f1.txt
utscsl@ubuntu:~/Documents/Encryption$ openssl enc -aes-128-cbc -e -in f1.txt -out f1cipher
r.bin -K 00112233445566778899aabbccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
utscsl@ubuntu:~/Documents/Encryption$ openssl enc -aes-128-cbc -d -in f1cipher.bin -out
f1NP.txt -K 00112233445566778899aabbccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
utscsl@ubuntu:~/Documents/Encryption$ openssl enc -aes-128-cbc -d -in f1cipher.bin -out f
1P.txt -K 00112233445566778899aabbccddeeff -iv 0102030405060708 -nopad
hex string is too short, padding with zero bytes to length
utscsl@ubuntu:~/Documents/Encryption$ hexdump -C f1NP.txt
00000000  31 32 33 34 35 36 37 38 39 30                [1234567890]
0000000a
utscsl@ubuntu:~/Documents/Encryption$ hexdump -C f1P.txt
00000000  31 32 33 34 35 36 37 38 39 30 06 06 06 06 06 06  [1234567890.....]
00000010
utscsl@ubuntu:~/Documents/Encryption$
```

3.4 Error Propagation – Corrupted Cipher Text

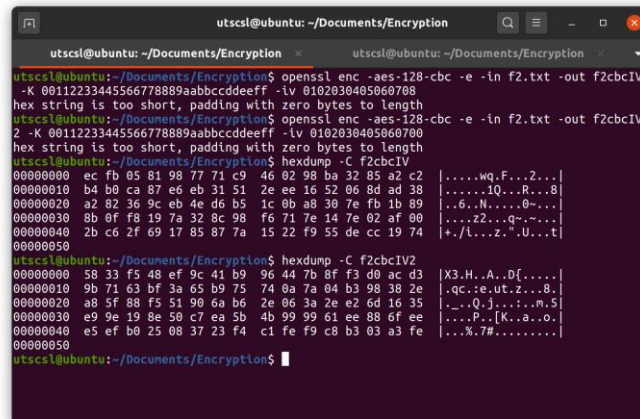

To understand the error propagation property of various encryption modes, we would like to do the following exercise:

Create a text file that is 64 bytes long.

Encrypt the file using the AES-128 cipher.

Unfortunately, a single bit of the encrypted file got corrupted. You can achieve this corruption using the bless hex editor.

Cryptography

```
utscsl@ubuntu: ~/Documents/Encryption
utscsl@ubuntu: ~/Documents/Encryption
utscsl@ubuntu:~/Documents/Encryption$ openssl enc -aes-128-cbc -e -in f2.txt -out f2cbcIV
-K 0011223344556677889aabbccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
utscsl@ubuntu:~/Documents/Encryption$ openssl enc -aes-128-cbc -e -in f2.txt -out f2cbcIV
2 -K 0011223344556677889aabbccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
utscsl@ubuntu:~/Documents/Encryption$ hexdump -C f2cbcIV
